4.3 Consumer contract tests between a web application and data provider

So far, we've been using the example of a web application and a user API that returns basic information about different users. In the GitHub project that we've provided, we'll now use a new example!

Let's imagine a web application communicating to a movies API. The web application is the consumer, while the movies API is the provider. The responsibility of the movies API is to return different movies and the year they were released to the web application. The web application contains different functions that query the movies API. For this example, we've decided to add both the consumer and provider in the same GitHub project to simplify the process, as shown in the following project structure:

```
> consumer-web
> data
> provider
package.json
package-lock.json
README.md
```

In the real world, this likely won't be the case. The consumers and data providers will live in separate projects, especially as more and more teams adopt a microservices architecture. But, to ease your understanding with contract testing, we've decided to keep everything in the same project so it's easier to follow.

4.3.1 Movies API overview

As mentioned, the movies API returns a list of movies to the consumer and has four important files:

- *movies.json*—A JSON file containing static data of movies
- *movies.js*—A class that represents a movie and what actions a user can perform
- *provider.js*—A class that contains all the logic to set up the example API
