The file movie.js is exported as `Movie` so our provider can call functions such as the following:

- `getMovies` for retrieving all the movies
- `getMovieById` for finding a movie that matches the ID provided and returns the matched movie
- `getMovieByName` for finding the movie that matches the name provided and returns the matched movie.
- `insertMovie` for inserting a new movie
- `getFirstMovie` for retrieving the first movie

As this is just an example project, we've kept this as simple as possible, but in real projects, these functions will have error handling and unit tests!

PROVIDER.JS

The file provider.js contains most of the code logic and has two main responsibilities, as shown in figure 4.5:

- Create the function to import the example data set from our movies.json file.
- Create the movies API and expose the different endpoints.
