consumer cares that they get the data shape they want from the contract agreement. For example, scenarios 4 and 5 define the provider to return the correct status code and a suitable error message. If the provider decides to update the error message, the contract should still pass because the consumer doesn't care about the actual value of the error message.

4.3.4 Writing the first consumer contract test

Let's start writing the consumer contract test for scenario 1. Writing the consumer contract test will be broken down into the following code:

- Importing the required dependencies
- Setting up the mock provider that the consumer will use
- Registering the expectation that the consumer has against the provider to the mock provider
- Calling the consumer against the mock provider
- Verifying the consumer test and generating the contract

IMPORTING THE REQUIRED DEPENDENCIES

In the consumer-web folder, create a new file called consumer-contract.spec.js, and add the following lines of code to import the required dependencies:

```
const path = require('path');
const { fetchMovies } = require('./consumer');
const { PactV3, MatchersV3 } = require('@pact-foundation/pact');
```

We require the `path` module to manage the file directory naming for our contract because we'll need to store the contract that Pact will generate. We also need the actual `consumer` and only need the `fetchMovies` function for now. Finally, we require both the `PactV3` and `MatchersV3` module from the Pact library.
