interactions that the consumer registered as part of the contract. The interactions are run against the actual service, so any other features or functionality that the data provider provides but that aren't needed by the consumer shouldn't be tested as part of contract testing.

Let's explain this with a simple scenario using the movies API and web application consumer, first introduced in chapter 4. One of the scenarios that the web consumer expects is when they send a `GET` request to the `movies` endpoint, the movies API should return the ID, name, and year the movie was released, as shown in figure 6.1.

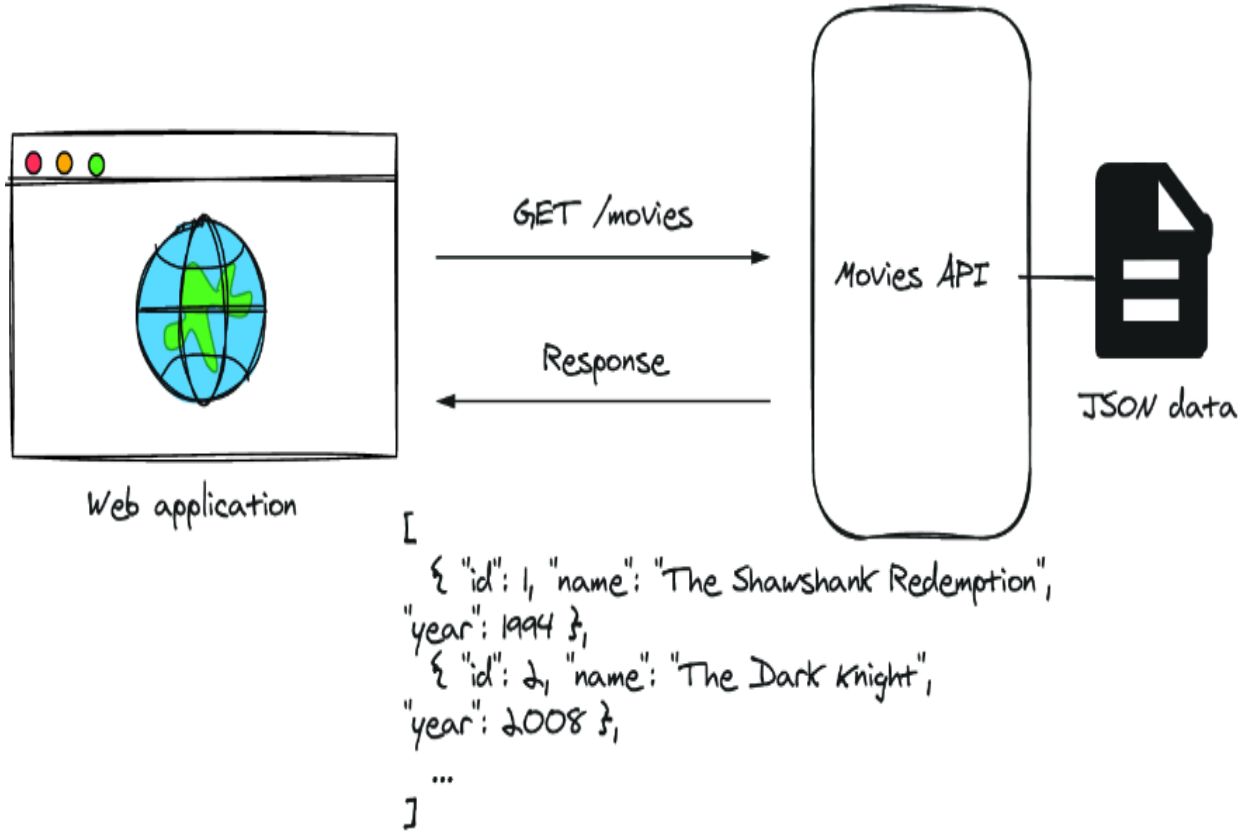

Figure 6.1 A web application sending a request to the movies API and the response it's expecting

A CDCT approach forces the data provider to develop only the consumer's required features. If the movies API introduces a breaking change that will update the `id` field from an integer to a string, the provider contract test should verify this change against the contract before deploying it to production.
