Figure 6.3 Example provider test run output

When you navigate back to PactFlow, you should see that the following contract has now been verified, as shown in figure 6.4.

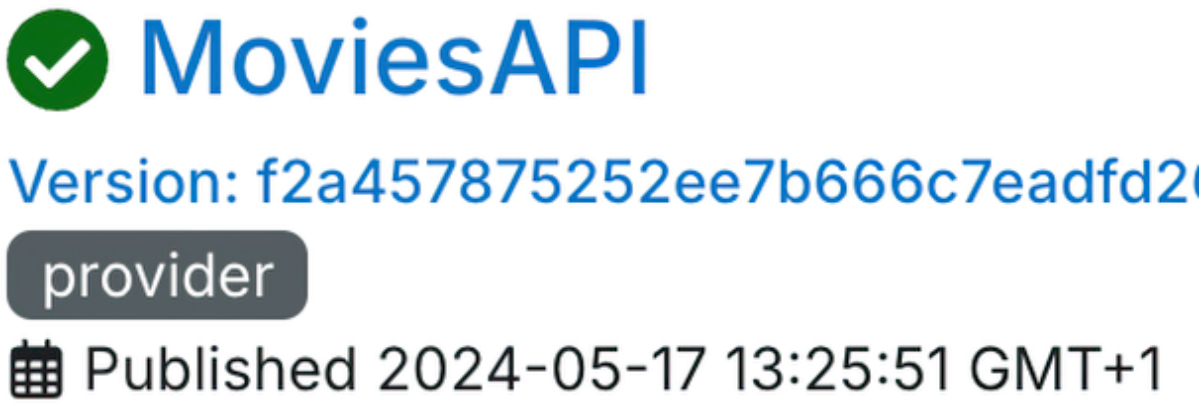

Figure 6.4 Consumer contract from WebConsumer verified by MoviesAPI provider

6.3.2 Introducing provider states

Now that you've verified the contract, things will get more interesting! If you remember from the scenarios that the web consumer defined in chapter 4, one of the scenarios was that they needed to request a specific movie. Let's revisit the scenario:

1. **Scenario: Get a single movie**

   Given there is a movies API

   When the consumer fetches a single movie

   Then the movies API should return a status code of 200

   And the ID, name, and year the movie was released.

When the consumer writes a contract test for this, most of the time, when the provider verifies the contract, the test will pass. But, in certain situations, this test could become flaky due to the movie being deleted by another team member or the test database being cleared. You don't necessarily want the contract test to fail when this situation arises. To solve this problem, we'll introduce provider states. Setting up provider states includes the following steps:
