Figure 7.1 A web consumer making multiple `GET` requests to different endpoints via the REST API to get all the necessary data can lead to under-fetching or over-fetching of data.

On the other hand, in GraphQL, consumers can send a single query and specify the data structure themselves, as shown in figure 7.2. In a GraphQL setting, consumers have full control of the data they want the server to return. This also eliminates the problem of under-fetching or over-fetching of data, which can also improve performance because consumers aren't making multiple requests.
