

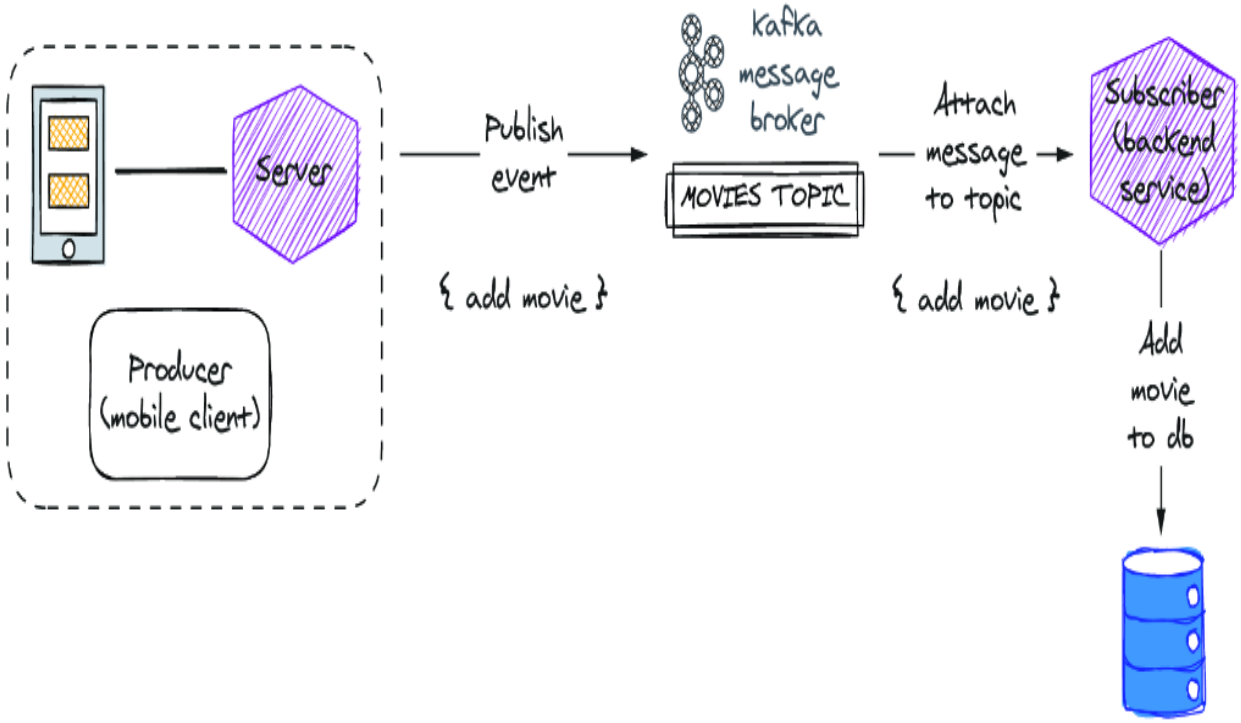

Figure 8.2 Event-driven architecture communicates via the Kafka message broker passing the message for CDCT from the producer via the "movies" topic to the subscriber.

In this chapter, we'll use CDCT for the following scenarios from the "movies" event service:

1. **Scenario: Add a new movie**

   Given that the movie doesn't exist

   When a producer publishes a message to add a new movie

   And the body includes the movie name and release date

   Then the message is published to the "movies" topic.

Concerning contract testing definitions, the subscriber relates to the consumer, and the producer equates to the provider, as shown in figure 8.3. The event consumer will publish the Pact contract to the Pact Broker with the expectations of the message contents. Then, the provider will replay the contract message contents against the real implementation to verify the Pact contract within the Pact Broker.
