

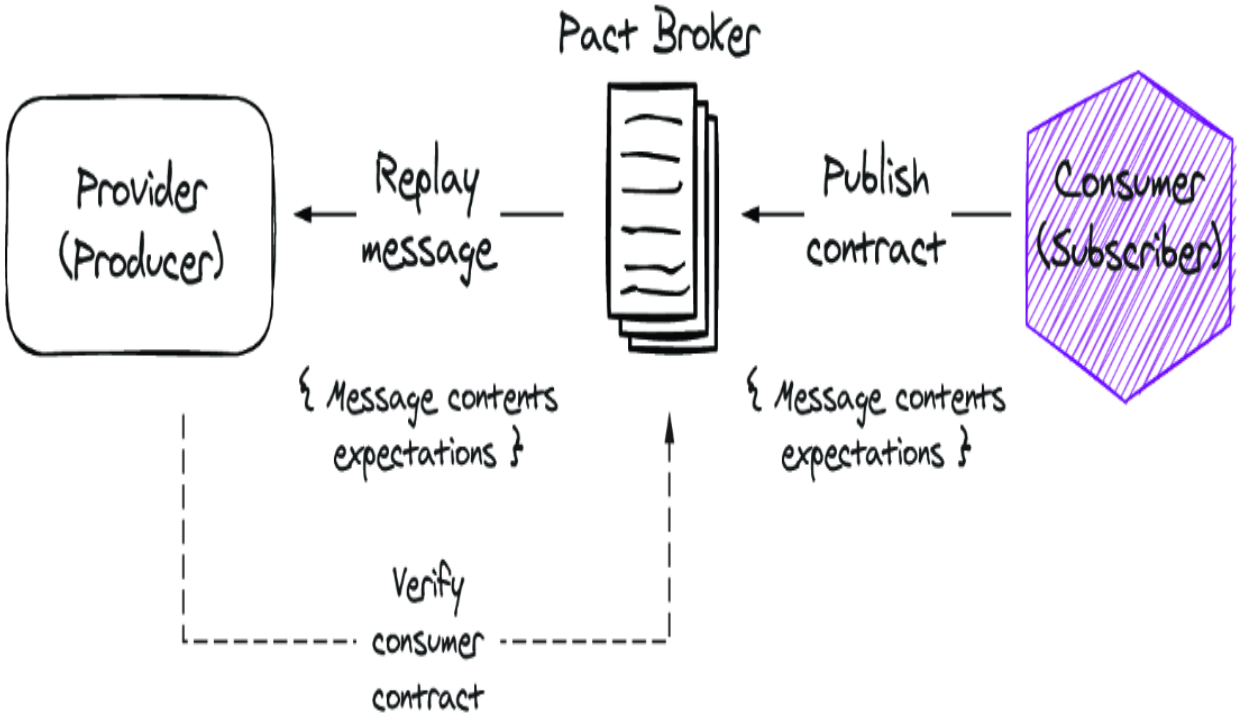

Figure 8.3 Showing the CDCT terminology and reversing the event flow with the Pact Broker in the middle

8.2 Pact consumer message setup with Kafka

We'll first focus on the construction of the event message by the producer and the consumer's handling of the event message. Focusing on the construction of the message and the message handler will answer the question of where the contract tests fit within the event code. We aren't experts in event architecture, so use the code in this chapter for reference, and apply your knowledge appropriately in your project. This section explains what you need regarding dependencies, asynchronous test functions, and all the steps of building consumer message Pact tests:

1. Use the pact-js (https://github.com/pact-foundation/pact-js) implementation of the consumer-driven contract library Pact.
2. Install dependencies using Node.js and npm.
3. Write the tests using the Jest framework.

You can follow along with the code in the project repository (https://github.com/mdcruz/pact-js-example/).
