8.2.1 Requirements

To follow along in this step-by-step tutorial, you need to have the following installed on your machine:

- Node.js
- Git and access to GitHub
- Docker (optional, only if you want to run the Kafka cluster)

To get started, navigate to our project's root folder in GitHub. We've added the dependencies to our package.json file, as shown in listing 8.1. The package to add is Pact from Pact foundation, Jest, and kafkajs.

Listing 8.1 package.json

```
"dependencies": {
    ...
    "kafkajs": "^2.2.4"
},
"devDependencies": {
    "@pact-foundation/pact": "12.1.0",
    "jest": "29.7.0"
}
```

8.3 Kafka consumer implementation

Now, we'll explain the implementation within our example event consumer. It's important to understand the code surrounding the section that consumes the message, so that it's clear what is tested via contract testing and what still needs to be tested by unit or integration tests. Let's look at the event handler within our service to provide context for the implementation, as shown in listing 8.2. This function (see figure 8.4) handles the following:

1. Taking the event message received
2. Converting it to the `Movie` object
3. Inserting the data into the database
