Before constructing the Pact interactions, the Pact consumer message configuration should be set up underneath the Jest `describe` section. The configuration includes the consumer and provider names, the folder to store the generated Pact files, and the log level for the test output, as shown in the following listing.

Listing 8.9 Pact message configuration

```
describe("Kafka handler", () => {
  const messagePact = new MessageConsumerPact({
    consumer: "ConsumerEvent",
    provider: "EventProducer",
    dir: path.resolve(process.cwd(), "pacts"),
    logLevel: "info",
  });
```

Once the message Pact has been configured, the next step is to build our Pact contract for the asynchronous body handler to verify, as shown in figure 8.8. To build the Pact contract, follow these steps:

1. Start with a description of the contract interaction.
2. Add message content.
3. Add event metadata.
