Listing 8.19 Movie event producer message

```
const produce = async (name, year) => {
    await producer.connect()
    const message = createMovie(name, year)
    await producer.send({
        topic,
        messages: [
          {
             key: "1",
             value: JSON.stringify(message)
          }
        ],
    })
}

module.exports = produce
```

The message content was set up using method `createMovie`. This function simply returns the added movie object, setting the values of `name` and `year` passed into the function. It's important to separate out the creation of the message content. So, however your project and code are set up, consider the fact that the Pact message framework is independent of any message broker. Therefore, the message content should be abstracted for the Pact test, as follows.

Listing 8.20 Create movie

```
function createMovie(name, year) {
    return {
        name: name,
        year: year,
    }
}

module.exports = {
    createMovie
}
```

Once the producer function has been implemented, the test can be added. To produce an event on the Kafka cluster for the "movies" topic, you can run the following package script:

```
npm run produce:kafka:message
```

The produce Kafka message script runs the index.js file, generating a message with key "1" and contents defined within the index file:
