argument and the metadata of the event as the second argument. In this example, as shown in listing 8.22, we're passing the `createMovie` function we set up earlier in listing 8.20.

**Listing 8.22 Message provider constructor**

```
    const provider = new MessageProviderPact({
      messageProviders: {
        'a movie add event': providerWithMetadata(() =>
          createMovie("The World's End", "2013"), {
            kafka_topic: 'movies'
        }),
      },
      logLevel: 'info',
      provider: 'EventProducer',
      providerVersion: '1.0.0',
      providerVersionBranch: 'main',
      pactBrokerUrl: process.env.PACT_BROKER_URL,
      pactBrokerToken: process.env.PACT_BROKER_TOKEN,
    });
```

Finally, the actual test block for the movie event provider is shown in listing 8.23. The test simply verifies the message provider set up within the message provider Pact constructor. The constructor defines the Pact Broker details, meaning that all contracts associated with the provider name `'EventProducer'` will be pulled down from the broker and verified, as shown in figure 8.15.

**Listing 8.23 Movie event provider test**

```
it('sends a valid movie', () => {
    return provider.verify();
});
```
