Summary

- PDCT is a type of static contract testing where two contracts—one representing consumer expectations and another representing the provider's capability—are compared to ensure they are compatible.
- PDCT allows consumers to use their favorite tools such as Cypress and WireMock to generate contracts.
- PDCT allows providers to use their favorite tools such as Postman and Dredd to verify contracts.
- In a PDCT approach, the consumer contract isn't tested against the provider code but against the provider contract in the form of an OpenAPI specification.
