Table A.1 Pros and cons for each form of Pact Broker

SaaS (PactFlow)	Own Storage Solution	Open Source
– Higher running costs; PactFlow provides a yearly subscription depending on the number of users, integrations, and features (though compared to cross-browser tools it's very cheap).	+ Low running costs; storage solutions such as AWS S3 or GitHub Enterprise are relatively cheap.	+ Low running costs; open source Pact Broker can be run in a container, which offers a cheap option. For example, with Amazon Elastic Container Service (Amazon ECS), you only pay for what you use.
+ Easy setup and free account; features such as user management and five free integrations means getting started is simple.	+ No barrier to getting started; adopting existing infrastructure reduces the barrier to getting sign-off for new tooling or provisioning new infrastructure.	– Infrastructure needs to be provisioned and configured; often new tools and infrastructure will need to go through an approval process that can cause delays.
+ Security authentication; an API token provides a secure way to interact with the Pact Broker and Single Sign-On (SSO) options such as GitHub or Google.	+ Slots into existing secure infrastructure; it has the ability to run within an existing secure network.	– Only username and password authentication method is available.
+ Additional features, including OpenAPI spec support; this means teams can use their existing contracts and adopt contract testing quickly.	– Lack of out-of-the-box contract testing features; logic will need to be configured around integrating with CI and also organizing the contracts logically.	+ Simple UI and core consumer contract testing features provide everything needed to adopt contract testing into CI and gain confidence from releasing microservices.
