Now that you've initialized an npm project, the next step is to add pact-js to your project. In the same folder and terminal, let's add pact-js by typing in the following command:

```
npm install --save-dev @pact-foundation/pact@12.1.0
```

This will install pact-js version 12.1.0 into your npm project's development dependencies. We've provided a version number here so that the code demonstration we'll use won't break, just in case Pact introduces breaking changes in future versions. Your package.json file will be updated and will have the following additional information:

```
"devDependencies": {
   "@pact-foundation/pact”: "^12.1.0"
}
```

If you want to install the latest version, you can run the following command instead:

```
npm install --save-dev @pact-foundation/pact@latest
```

That's it when setting up Pact locally on your machines. The preceding steps show in detail how to set up an npm project from scratch. However, most of the time, there's already an existing project to start with. In this case, you only need to install pact-js and not initialize an npm project. Let's look at how we can set this project up locally in one of two ways:

- Forking the project (recommended)
- Downloading the project

B.3 Forking the project

To clone the GitHub project locally, you need to have Git installed on your machines. If you don't have Git installed, head to their Downloads page at https://git-scm.com/downloads, and select the correct installer for your operating system. Once installed, type the following command into your terminal to verify the Git version:

```
git -v
```
