access.

3. The provider contract test is triggered manually from the provider pipeline. The provider retrieves the contract, replays the interactions, and verifies if the expected responses match the actual responses they provide.
4. If the provider verification is successful, the results of the verification are published, and the developer working on the consumer codebase gets feedback that their changes are safe to be deployed.
5. If the provider verification is unsuccessful, then the test fails. The developer working on the consumer codebase gets feedback that their changes aren’t safe to be deployed.
6. The developer fixes the problem, and the steps are repeated again until the provider verification is successful.

From a provider pipeline, a basic contract testing workflow can look like the illustration in figure 2.13.
