facilitates describing the JSON’s structure and any rules and constraints to validate the data up front. It sounds very similar to contracts, right? However, the difference with contracts here is that a schema can’t tell you how consumers use it and what fields aren’t used. In addition, schemas require teams to create a mechanism for change and evolution. Contract testing inherently captures breaking changes to ensure no consumers get left behind.

The contract content contains request and response data and all the details in the contract testing context. The contract also includes the following:

- The name of the consumer and provider
- Any state or data requirements for the request
- Any matching rules for dynamic values
- A unique contract version
- Environment and deployment tags

Listing 3.1 shows a contract example for a login scenario.
