

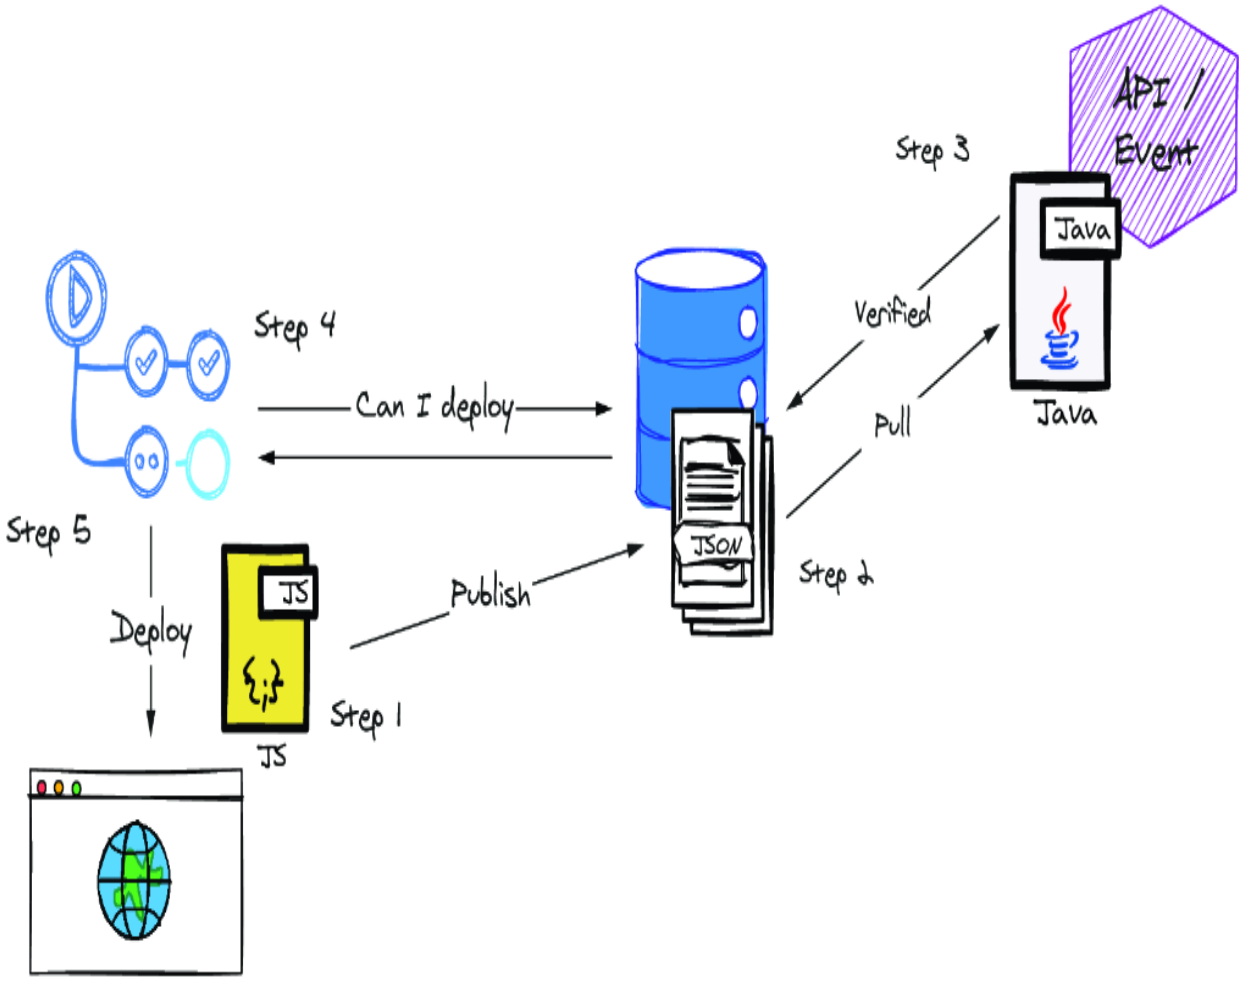

Figure 3.5 CDCT life cycle from a JavaScript web application, through the broker to Java API or event service, and finally using the can-i-deploy tool to verify the changes in the web application

3. The verification status is updated in the broker.
4. The consumer checks the contract verification status in the broker using the can-i-deploy tool.
5. The consumer deploys the changes.

The first step in the contract testing life cycle is to create the contract, whether generated from a web application, mobile application, or another service. The contract is generated from test code written in the consumer code and then published to the broker, which can also contain other consumer contracts, as shown in figure 3.6.
