

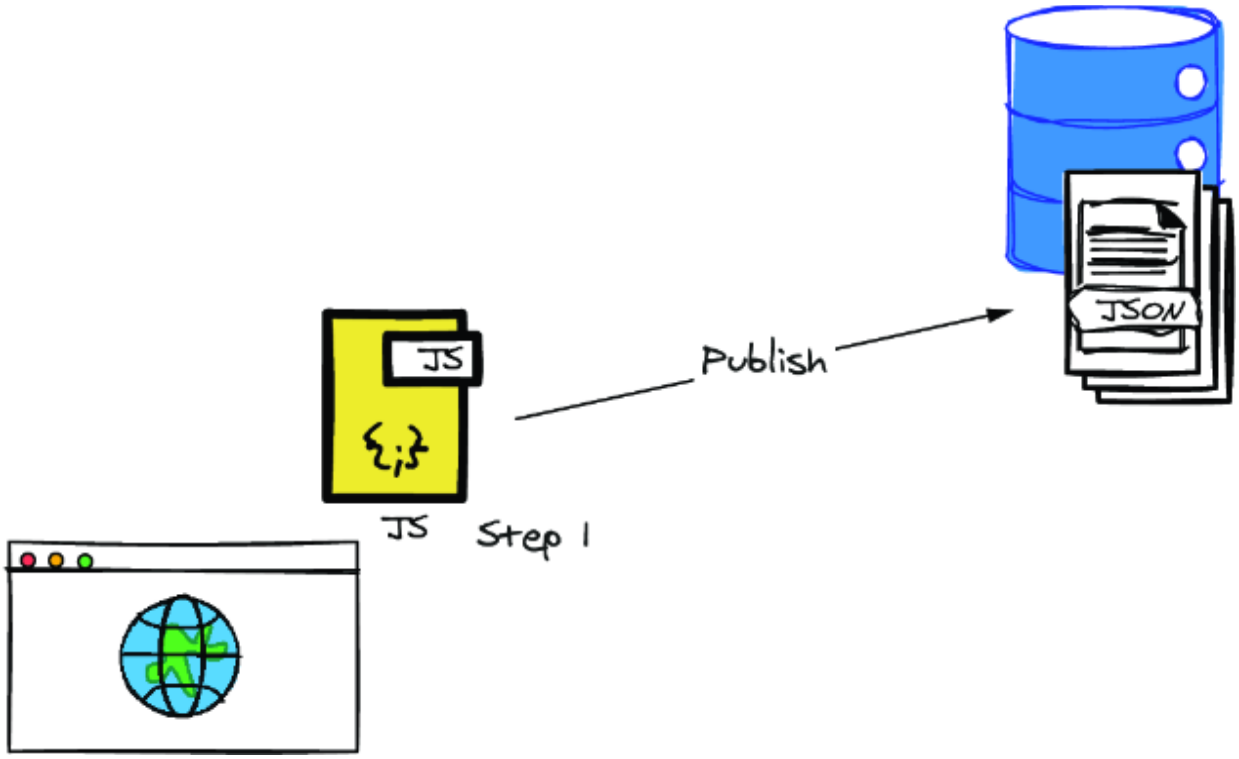

Figure 3.6 The contract is generated from the JavaScript test code and published to the broker.

Now that the contracts are available within the broker, the next step is for the provider to respond, as shown in figure 3.7. In this example, the provider pulls down the contract JSON document from the broker and replays the requests against their local service. When the provider tests run as part of a continuous integration (CI) pipeline, the contracts become successfully verified if there are no problems with consumer expectations and if the verification status for the specific version changes due to deployment is updated in the broker.
