```
        self.assertEqual(add_numbers(2, 3), 5)
        self.assertEqual(add_numbers(-1, 1), 0)

if __name__ == "__main__":
    unittest.main()
```

2.

Breakpoints Breakpoints allow you to pause program execution at a specific point and inspect the state of the program. This is especially useful when working with large codebases, as it allows you to examine the values of variables, memory, and the call stack. A breakpoint can be set in an Integrated Development Environment (IDE) or by using the `pdb` debugger in Python.

Example using `pdb`:

```
import pdb

def add_numbers(a, b):
    pdb.set_trace()  # Breakpoint
    return a + b

add_numbers(2, 3)
```

3. Once the breakpoint is hit, you can interact with the program's state, check variable values, and step through the code.
