the program runs, allowing the user to select an operation.

```
def show_menu():
    print("Select operation:")
    print("1. Add")
    print("2. Subtract")
    print("3. Multiply")
    print("4. Divide")
    print("5. Exit")
```

This function will print out a simple menu that includes options for all four operations and an option to exit the program. The user will input a number corresponding to their choice.

Step 3: Implementing User Input and Main Program Loop

Now, we'll implement the main loop that continuously asks the user for input until they choose to exit the program. We need to capture the user's choice from the menu and then take two numbers from the user for the operation they select.

```
def calculator():
    while True:
        # Show the menu
        show_menu()
```
