```
            print(f"{num1} * {num2} = {multiply(num1, num2)}")

    elif choice == '4':
            print(f"{num1} / {num2} = {divide(num1, num2)}")

    else:
            print("Invalid choice! Please select a valid option (1-5).")
```

Here's how this works:

- The program repeatedly displays the menu and prompts the user to choose an operation.
- It asks the user to input two numbers for the selected operation.
- If the user enters an invalid number, the program catches the error with a `try-except` block and prompts the user again.
- If the user selects an invalid menu option, the program will alert them to make a valid selection.
- The program keeps running until the user selects the 'Exit' option.

Step 4: Testing the Calculator

After defining the functions and the main program loop, we can test the calculator by calling the `calculator()` function.

```
if __name__ == "__main__":
    calculator()
```
