Here is how we can structure the student record:

```
students = {
    1: {'name': 'John Doe', 'age': 20, 'grade': 'A'},
    2: {'name': 'Jane Smith', 'age': 22, 'grade': 'B'}
}
```

In this structure:

- The **roll number** (e.g., 1, 2) is the key.
- Each student's **name**, **age**, and **grade** are stored as values in a nested dictionary.

**Step 2: Create Functions for CRUD Operations**

Now, let's define the functions that will handle each of the CRUD operations.

1. **Create (Add a Student):** This function will add a new student to the system by asking for the student's details (name, age, grade) and assigning a unique roll number.

```
def add_student(students):
    roll_number = int(input("Enter roll number: "))
    if roll_number in students:
        print("Error: Student with this roll number already exists.")
    else:
        name = input("Enter student name: ")
```
