- Handling invalid data types when entering student age or grade.
- Ensuring that only valid grades (such as A, B, C, etc.) are entered.

Conclusion

In this project, we have successfully built a **Student Management System (SMS)** using Python. We implemented CRUD operations to add, view, update, and delete student records. The program uses a dictionary to store student information and provides a simple console-based interface for interacting with the system.

You can further enhance this project by:

- Adding file handling to persist student data between sessions (e.g., saving records to a text file or database).
- Implementing a search feature to find students by name or grade.
- Adding more advanced validation checks, such as verifying valid age or grade inputs.
- Creating a GUI using a Python framework like Tkinter to make the system more user-friendly.

This project demonstrates how to manage data effectively using Python, and it serves as a great starting point for building more complex applications in the future.
