The basic steps for encrypting and decrypting a file with a Caesar Cipher are:

- **Encryption**: Shift each character of the text by a certain number (e.g., shift of 3).
- **Decryption**: Shift each character of the encrypted text back by the same number to recover the original message.

Here is a simple example:

- Original text: HELLO
- Shift (key) = 3
- Encrypted text: KHOOR

For decryption, we would shift the letters in the encrypted text by -3 to recover the original text.

Step 2: Create Functions for Encryption and Decryption

We will first write functions to handle the encryption and decryption processes using the Caesar Cipher.

1. **Encrypt Function**: This function will take the input text, shift each character by the given key, and return the encrypted text.

```
def encrypt(text, shift):
    encrypted_text = ""
    for char in text:
        if char.isalpha():
                # Shift the character within the alphabet
```
