```
            shifted = ord(char) + shift
            if char.islower():
                if shifted > ord('z'):
                    shifted -= 26
            elif char.isupper():
                if shifted > ord('Z'):
                    shifted -= 26
            encrypted_text += chr(shifted)
        else:
            # Non-alphabetic characters remain unchanged
            encrypted_text += char
    return encrypted_text
```

Explanation:

- The function iterates over each character in the text.
- If the character is alphabetic (either uppercase or lowercase), it shifts the character by the specified key (shift).
- Non-alphabetical characters, like spaces or punctuation, are not encrypted and are added to the result as is.
- The shift ensures that after 'Z' or 'z', it wraps around to the beginning of the alphabet (i.e., 'A' or 'a').
