- The `decrypt` function is very similar to the `encrypt` function, but instead of shifting forward, it shifts each character backward by the same key value.
- The algorithm ensures that if the shift goes past 'A' or 'a', it wraps around to the end of the alphabet.

---

**Step 3: Read and Write Files**

Now that we have functions to encrypt and decrypt text, we will create functions to read from and write to text files. The program will read the content of a file, encrypt or decrypt it based on user input, and then save the result back to a new file.

1. **Read File**: This function will open a file and return its contents as a string.

```
def read_file(file_path):
    try:
        with open(file_path, 'r') as file:
                content = file.read()
        return content
    except FileNotFoundError:
        print(f"Error: The file '{file_path}' was not found.")
        return None
```

2. **Write to File**: This function will write the encrypted or decrypted content back to a new file.

```
def write_to_file(file_path, content):
```
