```
    with open(file_path, 'w') as file:
        file.write(content)
    print(f"File saved as {file_path}")
```

Here:

- We use `with open()` to open files, ensuring the file is automatically closed after reading or writing.
- If the file does not exist when trying to read, a `FileNotFoundError` is handled.

Step 4: Implement the Main Program

We now need to create a main function that will integrate the above functionalities into a working program. This will allow the user to:

1. Choose whether they want to encrypt or decrypt a file.
2. Specify the file to process.
3. Input the encryption key (shift value).
4. Save the output to a new file.

```
def main():
    print("File Encryption Tool")
    print("1. Encrypt a file")
    print("2. Decrypt a file")
    print("3. Exit")
```
