Explanation:

- The `get_data()` function prompts the user to enter a list of numbers separated by spaces.
- It splits the input string by spaces, converts each part to an integer using `map()`, and stores the resulting list of integers.

Step 2: Sorting Algorithms

Sorting algorithms are fundamental in computer science and are used to arrange elements in a specific order. We will implement five common sorting algorithms.

1. Bubble Sort

Bubble Sort works by repeatedly stepping through the list, comparing adjacent elements, and swapping them if they are in the wrong order. The process continues until the list is sorted.

```
def bubble_sort(data):
    n = len(data)
    for i in range(n):
        for j in range(0, n-i-1):
                if data[j] > data[j+1]:
                    data[j], data[j+1] = data[j+1], data[j]  # Swap
    return data
```
