```
    data = json.load(f)
print(data)  # Output: {'name': 'Alice', 'age': 30}
```

-

7. `re` Module

The `re` module provides functions for working with regular expressions, allowing for pattern matching in strings.

`re.search(pattern, string)` : Searches for the first match of the pattern in the string.

```
import re
result = re.search(r'\d+', 'The number is 123')
print(result.group())  # Output: 123
```

-

`re.sub(pattern, replacement, string)` : Replaces occurrences of the pattern in the string with the replacement.

```
import re
result = re.sub(r'\d+', 'X', 'The number is 123')
print(result)  # Output: The number is X
```
