Chapter 3: Control Flow in C

Control flow refers to the order in which individual statements, instructions, or function calls are executed or evaluated. In C programming, control flow is achieved using conditional statements and loops. These constructs enable the creation of more dynamic and complex programs by allowing decisions to be made and code to be executed repeatedly based on certain conditions.

Conditional Statements

Conditional statements allow a program to make decisions based on specific conditions. The main types of conditional statements in C are:

1. **if Statement**
2. **if-else Statement**
3. **else-if Ladder**
4. **switch Statement**

1. if Statement

The `if` statement evaluates a condition, and if the condition is true, the code block inside the `if` statement is executed. If the condition is false, the code block is skipped.

Syntax:
