```
        for (int j = 1; j <= 2; j++) {
                printf("i = %d, j = %d\n", i, j);
        }
    }
    return 0;
}
```

Explanation:

In this nested loop, the inner loop runs completely for each iteration of the outer loop, resulting in 6 combinations of `i` and `j`.

Conclusion

Control flow structures in C are essential for making decisions and repeating tasks. By using conditional statements (`if`, `else`, `switch`) and loops (`for`, `while`, `do-while`), programmers can create dynamic and efficient code. Understanding and mastering these concepts is fundamental to becoming proficient in C programming.
