```
def example():
    print(x)  # Accessing global variable

example()
```

2.

Nonlocal Variables: Used inside nested functions to access variables from an enclosing function's scope.

```
def outer_function():
    x = 5

    def inner_function():
        nonlocal x
        x += 1
        print(x)

    inner_function()  # Outputs: 6

outer_function()
```

3.

4.2 Function Prototypes and Scope

Python functions don't require explicit prototypes like in some other languages (e.g., C or C++). However,
