1.4 Closing Files

Once you are done with a file, it should be closed using the `fclose()` function. Closing a file ensures that any changes are saved and that system resources are freed.

fclose(file);

---

2. File Modes and Operations

As mentioned earlier, file modes dictate the operations that can be performed on a file. Let's explore these file modes in more detail:

"r" (Read Mode): This mode is used when you need to open an existing file to read its content. If the file does not exist, an error is returned.

FILE *file = fopen("data.txt", "r");

-

"w" (Write Mode): When you open a file in write mode, the file is created if it doesn't exist. If the file already exists, its content is erased.

FILE *file = fopen("output.txt", "w");
