- Since macros are expanded directly in the code, they can lead to difficult-to-debug errors (like incorrect evaluation order in complex expressions).
- Macros do not have type safety, so they can be prone to errors if used improperly (e.g., passing a complex expression like `SQUARE(a + b)`).

9.1.3 Conditional Compilation

Conditional compilation is a mechanism by which the compiler includes or excludes certain portions of code based on certain conditions. This is useful for compiling code for different platforms or debugging. The most common preprocessor directives used for conditional compilation are:

- **#ifdef** : This checks if a macro is defined.
- **#ifndef** : This checks if a macro is not defined.
- **#endif** : Marks the end of a conditional block.
- **#else** : Specifies an alternative block to compile if the condition is false.
- **#elif** : Checks another condition if the previous ones failed.

For example:

```
#define DEBUG

#ifdef DEBUG
    printf("Debugging mode is enabled.\n");
#endif
```
