- **`argc` (Argument Count)**: The number of arguments passed to the program, including the program's name.
- **`argv` (Argument Vector)**: An array of strings (character pointers) that holds each argument passed to the program.

The syntax of the `main()` function with command-line arguments is as follows:

```
int main(int argc, char *argv[])
```

For example, if you run the program like this:

```
$ ./program arg1 arg2 arg3
```

- `argc` will be 4 (because there are four elements: the program name and the three arguments).
- `argv[0]` will be the program name (`./program`).
- `argv[1]` will be `arg1` , `argv[2]` will be `arg2` , and so on.

9.3.2 Example Program Using Command-Line Arguments

```
#include <stdio.h>

int main(int argc, char *argv[]) {
    printf("Number of arguments: %d\n", argc);
    for (int i = 0; i < argc; i++) {
        printf("Argument %d: %s\n", i, argv[i]);
```
