In the src/main/resources/db/migration folder for the Order Service project, create a new V2__Add_user_audit.sql migration script to add two new columns to the `orders` table. Ensure you type two underscores after the version number.

Listing 12.29 Adding new audit metadata to the `orders` table

```
ALTER TABLE orders
  ADD COLUMN created_by varchar(255);          ❶
ALTER TABLE orders
  ADD COLUMN last_modified_by varchar(255);    ❷
```

❶ Add a column for the username of who created the row.

❷ Add a column for the username of who last updated the row.

ENSURING USER DATA PRIVACY

There's one last requirement we haven't covered yet: ensuring that order data is only accessed by the users who created the orders. No user should be able to see the orders from another person.

There are a few different solutions for implementing this requirement in Spring. We'll follow these steps:

1. Add a custom query to `OrderRepository` to filter orders based on the user who created them.
2. Update `OrderService` to use the new query instead of the default `findAll()`.
3. Update `OrderController` to extract the username of the currently authenticated user from the security context and pass it to `OrderService` when asking for orders.
