(`/actuator/health/liveness`) and readiness (`/actuator/health/readiness`) states, as illustrated in figure 13.4:

- *Liveness state*—When an application is not live, this means it has entered a faulty internal state from which it won't recover. By default, Kubernetes will try restarting it to fix the problem.
- *Readiness state*—When an application is not ready, this means it can't process new requests, either because it's still initializing all its components (during the startup phase) or because it's overloaded. Kubernetes will stop forwarding requests to that instance until it's ready to accept new requests again.
