With this change, all metrics will have an `application` label with the application name, which is very useful when querying metrics and building dashboards to visualize them in Grafana:

```
jvm_threads_states_threads{application="catalog-service",
➥state="waiting",} 13.0
```

You have already encountered Grafana when working with logs. Just as you browsed logs using Loki as a data source for Grafana, you can query metrics using Prometheus as a data source. Furthermore, you can use the metrics stored by Prometheus to define dashboards, graphically visualize data, and set alarms or notifications when certain metrics return known critical values. For example, when the rate of failing HTTP requests per minute goes above a certain threshold, you might want to get an alarm or a notification so you can act on it. Figure 13.5 illustrates the monitoring architecture.
