Feel free to apply what you've learned in this chapter to all the applications in the Polar Bookshop system. You'll need these updated applications in the next chapter, where we'll deploy everything in production.

1. Disable the Spring Cloud Config client.
2. Define a base Kustomization manifest, and update Tilt and the commit stage workflow.
3. Use Kustomize to generate a ConfigMap.
4. Configure a staging overlay.

You can refer to the Chapter14/14-end folder in the code repository accompanying the book to check the final result (https://github.com/ThomasVitale/cloud-native-spring-in-action).

Summary

- A configuration server built with Spring Cloud Config Server can be protected with any of the features offered by Spring Security. For example, you can require a client to use HTTP Basic authentication to access the configuration endpoints exposed by the server.
- Configuration data in a Spring Boot application can be reloaded by calling the `/actuator/refresh` endpoint exposed by Spring Boot Actuator.
- To propagate the config refresh operation to other applications in the system, you can use Spring Cloud Bus.
