We mentioned earlier that Pyrra effectively converts `ServiceLevelObjective` resources into Prometheus recording rules. How does that look? If you take listing 10.3 as an input, the respective output (which you will also find on your local drive in the `prometheus_pyrra/` directory), is shown in the following listing (note that this file has some 94 lines overall, so we only show the first rule here).

Listing 10.4 Prometheus recording rules derived from `ServiceLevelObjective`

```
groups:
- interval: 1m
  name: ho11y-api-query-increase
  rules:
  - expr: sum by(http_status_code) (increase(ho11y_total{job="svc"}[1w]))
    labels:
      job: svc
      slo: ho11y-api-query
    record: ho11y:increase1w
  - alert: SLOMetricAbsent
    expr: absent(ho11y_total{job="svc"}) == 1
    for: 1m
    labels:
      job: svc
      severity: critical
      slo: ho11y-api-query
...
```

Now, let's see it in action. Head over to http://localhost:9099/ in your browser, and you should see something like figure 10.2, the Pyrra landing page, providing an overview of all SLOs.

Figure 10.2 Pyrra landing page (SLO list)

Figure 10.3 depicts the Prometheus SLO. You can see that we're in compliance (the SLO is met).
