

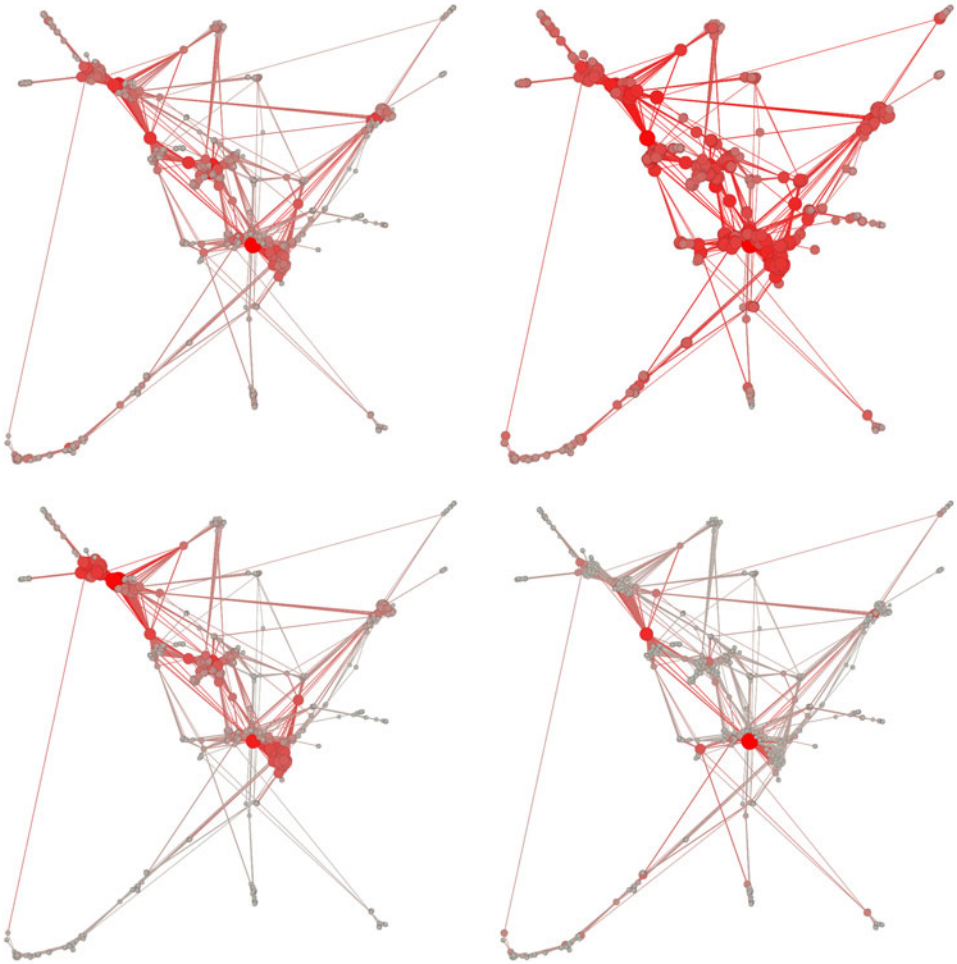

Figure 6.10 The same network measured using degree centrality (top left), closeness centrality (top right), eigenvector centrality (bottom left), and betweenness centrality (bottom right). More-central nodes are larger and bright red, whereas less-central nodes are smaller and gray. Notice that although some nodes are central according to all measures, their relative centrality varies, as does the overall centrality of other nodes.

CENTRALITY

Networks are representations of systems, and one of the things you want to know about the nodes in a system is which ones are more important than the others, referred to as *centrality*. Central nodes are considered to have more power or influence in a network. There are many different measurements of centrality, a few of which are shown in figure 6.10, and different measures more accurately assess centrality in different network types. One measure of centrality is computed by D3's `force()` layout: degree centrality.
