Builds a scale that maps impact to a ramp from white to dark red

```
var colorScale = d3.scale.linear()
                   .domain([0,maxImpact]).range(["white","#990000"]);

d3.select("svg")
  .selectAll("circle")
  .data(incomingData)
  .enter()
  .append("circle")
  .attr("r", function(d) {return radiusScale(d.impact);})
  .attr("cx", function(d,i) {return timeRamp(d.tweetTime);})
  .attr("cy", function(d) {return 480 - yScale(d.impact);})
  .style("fill", function(d) {return colorScale(d.impact);})
  .style("stroke", "black")
  .style("stroke-width", "1px");
};
```

Size, color, and vertical position will all be based on impact

As shown in figure 2.23, each tweet is positioned vertically based on impact and horizontally based on time. Each tweet is also sized by impact and colored darker red based on impact. Later on we'll want to use color, size, and position for different attributes of the data, but for now we'll tie most of them to impact.

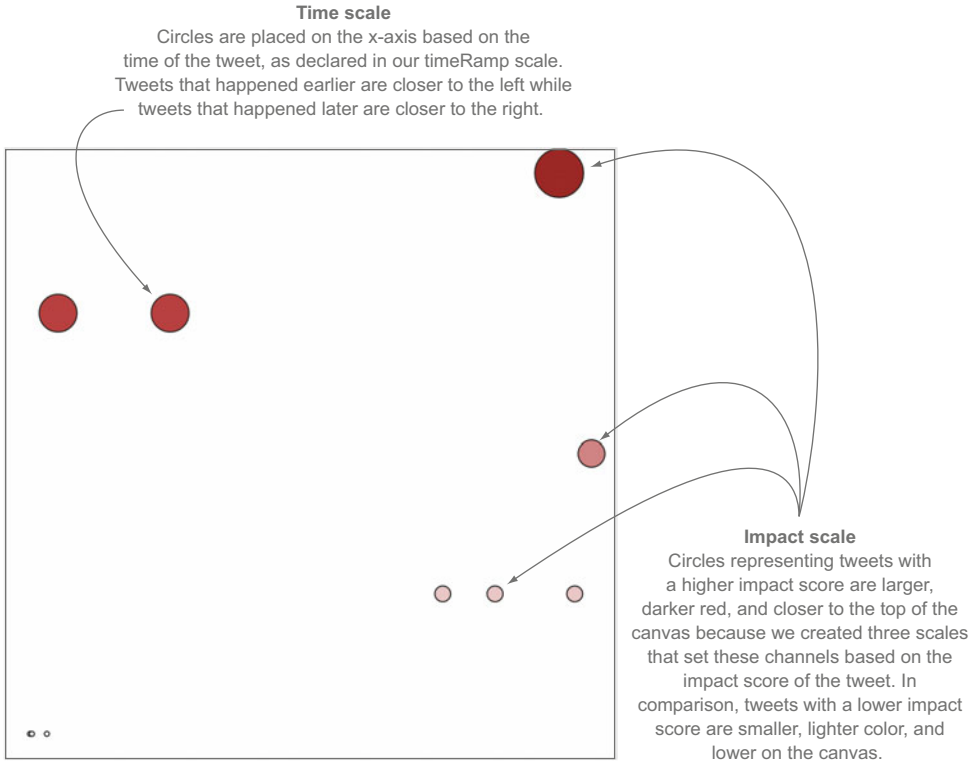

Figure 2.23 Tweets are represented as circles sized by the total number of favorites and retweets, and are placed on the canvas along the x-axis based on the time of the tweet and along the y-axis according to the same impact factor used to size the circles. Two tweets with the same impact factor that were made at nearly the same time are shown overlapping at the bottom left.
