

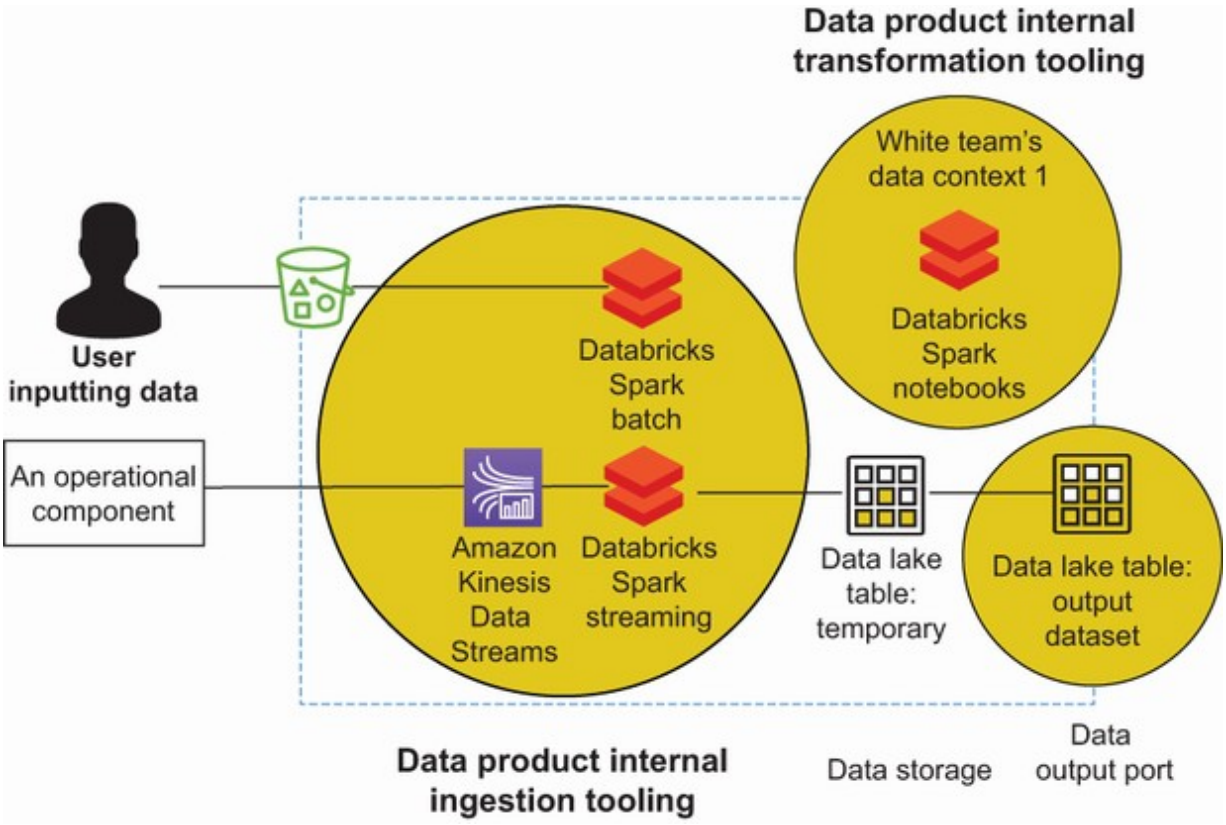

Figure 8.10 The White team uses Databricks to take streaming as well as push-based data to build a new data product.

The second data product of the White team shows how simple it is to build additional derived data products using Databricks. The team simply has to pick up another notebook, source the two data products already provided, and transform them into a third new data product inside Databricks.

Business analysts can easily use Databricks SQL to access and browse the data products. They can also create reports and dashboards inside that framework.

On Databricks, the workflows are quite Databricks-specific, and the principles work out a bit differently. So we'll cover them together in one section, highlighting why this change can be a pro for this architecture.

8.3.4 Workflow considerations
