because of its focus on data productization, loosening the data coupling, and domain-focused shift in ownership.

DATA VOLUME

Companies working with high volumes of data may experience bottlenecks in cost and time as data is transformed and transferred. These bottlenecks are harrowing in the case of centralized architectures, as data needs to be imported from all the sources into a central lake to be transformed and queried.

If your company operations require time minimization between data generation and analysis or consumption (that is scalable and near real time), then ownership decentralization and data productization may work for more-efficient high-volume data processing. Figure 2.2 depicts the summary of domain-data drivers for a data mesh.
