2.3.2 Development cycle in the shoveling example

In the first chapter, we described how Candace introduced a data mesh into her organization's work:

1. She identified the business case: profits were low, and data utilization was overly complicated and inefficient.
2. She prepared for the project.
    1. She appointed herself as an enabler and read *Data Mesh in Action* from cover to cover.
    2. She divided her business into domains and pushed ownership of data, information, and some decisions to the main domains of her operations. Instead of collecting their raw data to later transform and analyze, she presented domain owners the problem. They collectively agreed that Adam and Eve would work with their data and come up with a decision-pricing model for their streets.

It's worth noting that she profited even before the first development cycle started! The next year, the team went through the first development iteration:

1. The business goal was developed to improve the procurement forecast.
2. The data products were defined: Adam's and Eve's shovel use estimations.
3. The data products were developed: online spreadsheets for Adam and Eve.
4. She reviewed the results and planned the next cycle iteration.

As you can see, the first data mesh implementation cycle doesn't have to be long or strenuous, or encompass all the data mesh properties to bring the business value. We will expand on this topic in chapter 4. There, we use the example of Messflix to show how a data mesh MVP could be implemented within a month. For now, let's learn a bit more about cycle elements.

2.3.3 Enabling the team
