

Figure 6.11 – The data lineage DAG for our training_set table

For our DAG, we clicked the left **+** button on the `store_holidays_ft` table and again on the `regional_holidays_silver` to expand the lineage even further. You can continue to explore by clicking the **+** buttons on the lineage DAG in your workspace as well. The DAGs for every table saved in Unity Catalog are updated whenever the table itself or its sources are altered, making it living documentation (this is great news for those of us who despise creating and maintaining documentation!).

Creating a baseline model with AutoML

Now, let's create a baseline model using AutoML. There are two ways to complete this. You can use the UI or the API. The project notebook `CH6-01-Building Favorita Baseline Model` has the necessary Python code to run the baseline experiment using the API. If you choose to run the code, check the notebook for the experiment information as in *Figure 6.2*. If you want to create the baseline model using the UI, you can start by selecting the **+ New** button on the left sidebar. Then in the Machine Learning section, choose **AutoML Experiment**. See the experiment configurations in *Figure 6.12* to set up the experiment. Please note that you need to have a cluster running before you can select it from the Cluster dropdown menu. You do not need GPUs for this part; A CPU-based cluster works fine.
