When you execute this cell, you will see a sample of images and their predicted labels, similar to what is shown in *Figure 6.33*. Scan the results to get an idea of the model's accuracy.

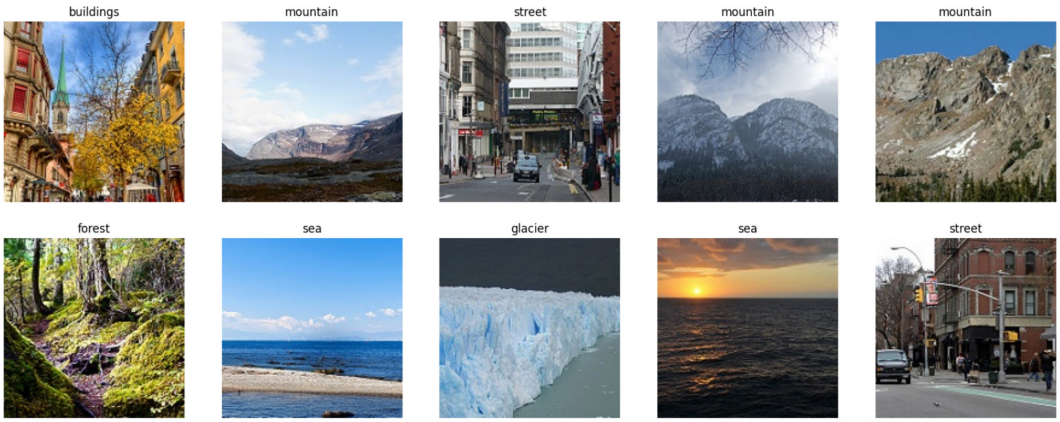

Figure 6.33 – The images and their labels

The `Ch6-02` notebook includes a markdown example of code that can calculate your score on the exact label prediction. In our case, we leverage binary classification by scoring the model using the one-vs-all method. Recall that while training our model we were transforming our images, and it is a good practice to keep this transformation when scoring as well. To do so, we create the function `feature_extractor`.

```
def feature_extractor(img):
    image = Image.open(io.BytesIO(img))
    transform = transform_tests = torchvision.transforms.Compose([
        transforms.Resize((150,150)),
        transforms.RandomHorizontalFlip(p=0.8), # randomly flip and rotate
        transforms.ColorJitter(0.3,0.4,0.4,0.2),
        transforms.ToTensor(),
        transforms.Normalize((0.425, 0.415, 0.405), (0.205, 0.205, 0.205))
        ])
    return transform(image)

# to reduce time on loading we broadcast our model to each executor
model_b = sc.broadcast(loaded_model.model)
```
