Workflows

Databricks Workflows is a flexible orchestration tool for productionizing and automating machine learning projects. Workflows help the ML lifecycle by providing a unified way to chain together all aspects of machine learning, from data preparation to model deployment. With Databricks Workflows, you can designate dependencies between tasks to ensure tasks are completed in the required order. These dependencies are visualized with the arrows connecting the tasks, as shown in *Figure 7.2*.

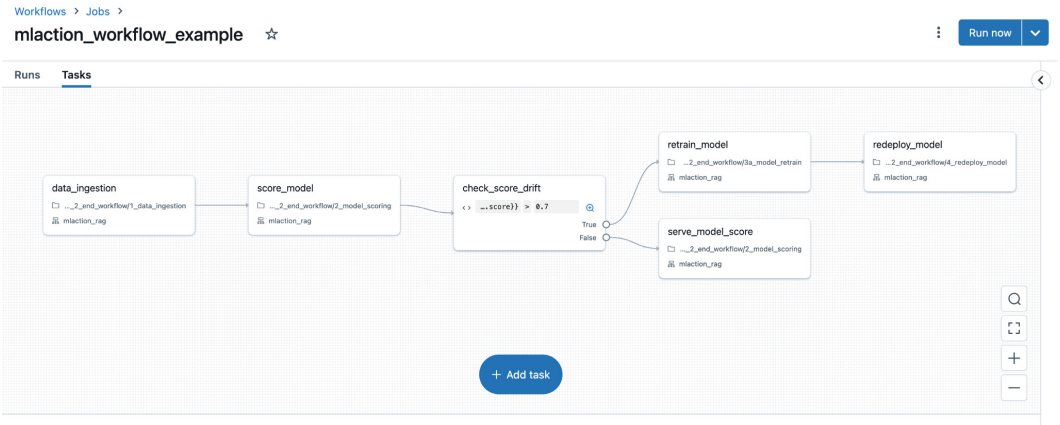

Figure 7.2 – A Databricks workflow with five tasks, with the feature engineering task having two dependencies

Tasks in a workflow are not limited to notebooks. In *Chapter 3*, we prepared a DLT pipeline to prepare data in the Bronze layer, and DLT pipelines can be a workflow component. Additional objects, like JAR files, python scripts, and SQL, can be tasks within a workflow, as shown in *Figure 7.3*.
