As you can see from the `grading_prompt`, we've designed this metric to give a score between one and five, where a score of one identifies text as casual and a five evaluates text as noticeably formal. This is a powerful tool to evaluate your model based on criteria important to your business use case. You can modify the template according to your needs. We also add in examples of the metric, defined below in *Figure 7.54*.

```
# Adding custom professionalism metric
professionalism_example = EvaluationExample(
    input="What is MLflow?",
    output=(
        "MLflow is like your friendly neighborhood toolkit for managing your machine
        learning projects. It helps "
        "you track experiments, package your code and models, and collaborate with
        your team, making the whole ML "
        "workflow smoother. It's like your Swiss Army knife for machine learning!"
    ),
    score=2,
    justification=(
        "The response is written in a casual tone. It uses contractions, filler words
        such as 'like', and "
        "exclamation points, which make it sound less professional. "
    )
)
```

Figure 7.54 – Adding an example for the custom professionalism metric

With our professionalism metric, let's run the model evaluation using MLfLow. To run an evaluation, we call `mlflow.evaluate()` against the Pandas DataFrame containing the questions, ground truth answers, and chatbot-generated answers. We include the answer correctness and professionalism metrics as extra metrics. The code below will calculate many other metrics in addition to the two we specified, such as token count, toxicity, and Automated Readability Index grade (the approximate grade level required to comprehend the text).
